

# FULL-STACK NANODEGREE SESSION 3

AJIROGHENE SUNDAY

# GENERAL DISCUSSION

10 MINS

# TOPIC REFRESHER

10 MINS

1. **CONSIDER A SIMPLE DATABASE TABLE OF < People > WITH THE FOLLOWING RECORDS:**

**ID: 1, NAME: TOLU**

**ID: 2, NAME: ABEL**

**ID: 3, NAME: SHOLA**

**ID: 4, NAME: EJIRO**

**ID: 5, NAME: AKPOS**

**WHAT FOLLOWING COMMAND ENABLES GETTING ALL ITEMS FROM people TABLE**

people.query()

people.query.all()

people.query\_all()

people.query.filter\_by()

None

A

B

C

D

E

## 2 WHAT WILL THE FOLLOWING COMMAND RETURNS TO US:

`Person.query.filter_by(name='abel').all()`

### 3 WHAT WILL THE FOLLOWING COMMAND RETURNS TO US:

Person.query.filter\_by(name='abel')

#### 4 WHAT WILL THE FOLLOWING COMMAND RETURNS TO US:

```
person = Person.query.filter_by(name='abel').first()
```

```
person.name
```

<id: 2, name: 'ABEL'>

< name: 'ABEL'>

ABEL

'ABEL'

None of the above

A

B

C

D

E

## 5 WHAT WILL THE FOLLOWING COMMAND DO TO THE EXISTING TABLE <people> IN THE DATABASE:

```
person = People(name="ajioz")  
db.session.add(person)  
db.session.commit()
```

Add a new record of  
<name: 'Ajioz'> to the  
end of the table  
<Person>

Add a new record of  
<name: 'Ajioz'> to the  
beginning of the table  
<Person>

Does nothing until  
"db.session.rollback()" is  
entered

Spilt back an error with  
the following status  
code  
<flask\_sqlalchemy.Bas  
eQuery object at  
<[location]>

None of the above

A

B

C

D

E

**6 A DEVELOPER DECIDED TO ADD MULTIPLE RECORDS INTO THE EXISTING TABLE <people> IN A DATABASE, CONSIDER WHICH OF THE FOLLOWING COMMAND IS MOST APPROPRIATE USING SQLALCHEMY**

```
person1 = People(name="ajioz")
person2 = People(name="Toyin")
db.session.add_all([person1], [person2])
db.session.commit()
```

**A**

```
person1 = People(name="ajioz")
person2 = People(name="Toyin")
db.session.add([person1], [person2])
db.session.commit()
```

**B**

```
person1 = People(name="ajioz")
person2 = People(name="Toyin")
db.session.add_all([person1], [person2])
db.session.commit()
db.session.rollback()
```

**C**

## BONUS: MIND REWIND ON SQLALCHEMY ORM

### Model.query

Filter result that passes  
this query

Person.query.filter\_by(name='Amy')

Person.query.all()

Filter all result in the db  
table

Person.query.count()

Same as SQL count

Person.query.filter(Person.name == 'Amy')

Spot the error

Person.query.filter(Person.name == 'Amy', Team.name == 'Udacity')

Person.query.get(1) ← gets by primary key

Get object by its primary key

## BONUS: MIND REWIND ON SQLALCHEMY ORM

**Model**.query

---

```
Product.query.filter_by(category='Misc').delete()
```

# BONUS: MIND REWIND ON SQLALCHEMY ORM

## OBJECT LIFE-CYCLE

`db.session`

It isn't until we execute `db.session.commit()` that we commit anything to the database

- Not until we execute the `db.session.commit()`, we haven't committed or persisted any data to the db
- Every time we want to interact with the database, we start the connection and end the connection when all the interactions are done
- Within that interaction session, we create transaction that we commit into the db
- Proposed database change are not immediately committed to the db, once defined. Changes go through stages in order to provide the ability to "undo" a mistake before committing it to a db

# BONUS: MIND REWIND ON SQLALCHEMY ORM

## OBJECT LIFE-CYCLE

### Object lifecycle

```
user1 = User(name='Amy')
```

#### Transient:

Object exists, unassociated to a Session

INSERT

```
session.add(user1)  
session.add_all([user1, user2])
```

#### Pending:

Object is associated to a Session object.  
"Undo" is available (as rollback)

```
session.rollback()
```

If called before flush  
occurs on session

UPDATE

```
user1.name = 'New Name for Amy'
```

DELETE

```
session.delete(user1)
```

**An object stays in a pending state  
until a *flush* happens.**

- First is defining an object, in a floating state.
- It isn't we call `session.add(user1)` Or `session.add_all()`, or `session.delete()` or we do something to model like the update method that we end up proposing an action to the db. At this point the object is in pending state
- At the pending state it is said to be associated to a session object but we haven't committed it yet, at this stage one can decide to rollback so long flush hasn't yet happen.
- Flush takes pending changes and translate them into SQL commands ready to be committed to db
- Flush occurs under the hood, once you call `de.session.commit()` to get the data persisted

# BONUS: MIND REWIND ON SQLALCHEMY ORM OBJECT LIFE-CYCLE

Calling Query flushes pending changes added to session

---

```
# db.session.add(person)      ← Adds pending change to a transaction
# db.session.add_all([p1, p2]) (db.session always works within a transaction)
# db.session.delete(p3)
```

➤ The one way Flushes occurs

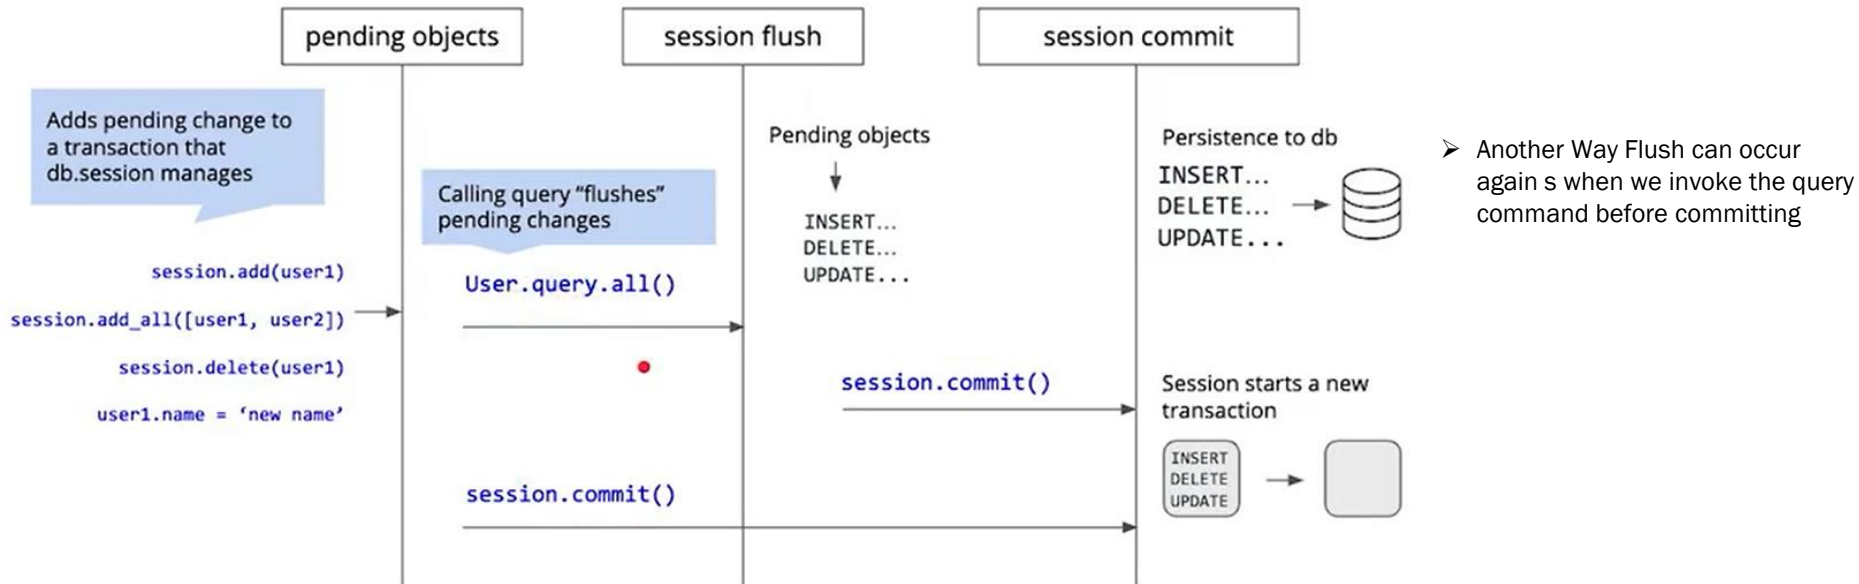

```
# Person.query.first()
```

↖ Calling query "flushes" pending changes

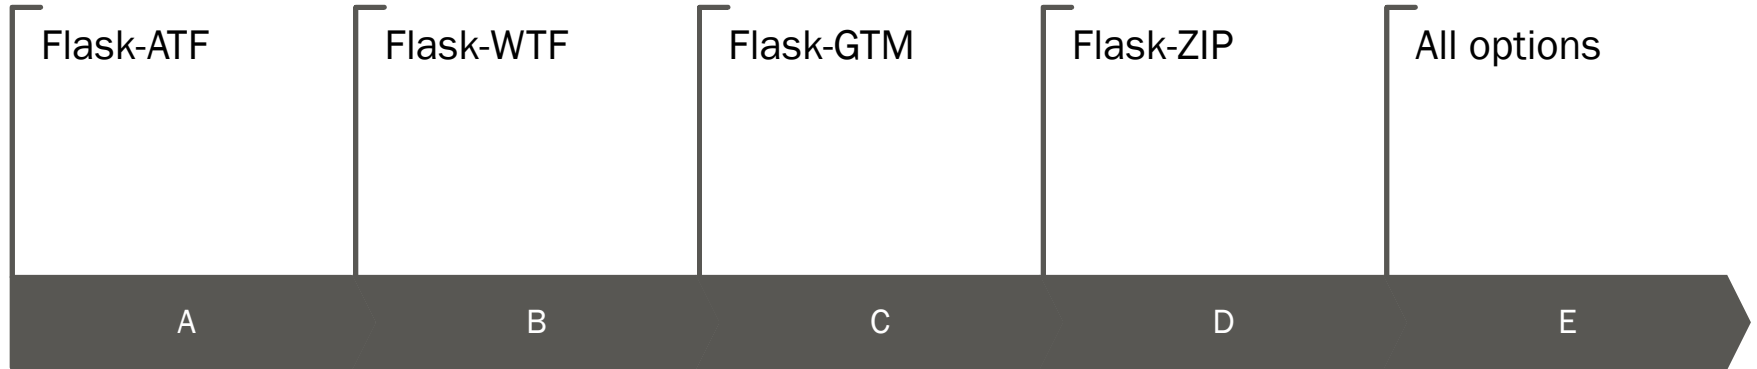

db.session.commit() still needs to be called after a flush.

# BONUS: MIND REWIND ON SQLALCHEMY ORM OBJECT LIFE-CYCLE

## Object lifecycle

## 7 FORMS IN FLASK CAN BE IMPLEMENTED BY USING AN EXTENSION CALLED ?

## 8. FLASK WORKS WITH MOST OF THE RDBMSS, SUCH AS?

PostgreSQL	MySQL	SQLite	All of the above	None of the above
A	B	C	D	E

9. THE \_\_\_\_\_ DECORATOR IN FLASK IS USED TO BIND URL TO A FUNCTION.

# Table of contents

SQLAlchemy In  
Depth- by  
student

02  
Migrations  
Why Migrations

03  
Building our hello app with  
migrations

04  
Our next step forward  
FLASK APP

02

# MIGRATIONS

# What to expect

- What are migrations
- Why we use migrations
- How to install necessary libraries
- Steps to get migrations going
- Upgrades and Downgrades

# Takeaways

- Migrations deal with how we manage modifications to our data schema, over time.
- Mistakes to our database schema are very expensive to make. The entire app can go down, so we want to
  - quickly roll back changes, and
  - test changes before we make them
- A Migration is a file that keeps track of changes to our database schema (structure of our database).
  - Offers version control on our schema.

# Takeaways (Upgrades and rollbacks)

- Migrations stack together in order to form the latest version of our database schema
- We can upgrade our database schema by applying migrations
- We can roll back our database schema to a former version by reverting migrations that we applied

Why are migrations necessary

QA SESSION

# Migrations (Command-line scripts)

- **migrate**: creating a migration script template to fill out; generating a migration file based on changes to be made
- **upgrade**: applying migrations that hadn't been applied yet ("upgrading" our database)
- **downgrade**: rolling back applied migrations that were problematic ("downgrading" our database)

# REQUIREMENTS

Flask-Migrate is our library for migrating changes using SQLAlchemy. It uses a library called Alembic underneath the hood

Flask-Migrate (flask\_migrate) is our migration manager for migrating SQLAlchemy-based database changes

The second library that we're using is called Flask-Script  
Flask-Script (flask\_script) lets us run migration scripts we defined, from the terminal.

# REQUIREMENTS

You can install Flask-Migrate (flask\_migrate) and Flask-Script (flask\_script) using pip3 or pip if you haven't

To install Flask-Migrate run `pip3 install Flask-Migrate`

# STEPS

1. Initialize the migration repository structure for storing migrations

Command: ( flask db init)

2. Create a migration script (using Flask-Migrate)

Command: (flask db migrate)

3. (Manually) Run the migration script (using Flask-Script)

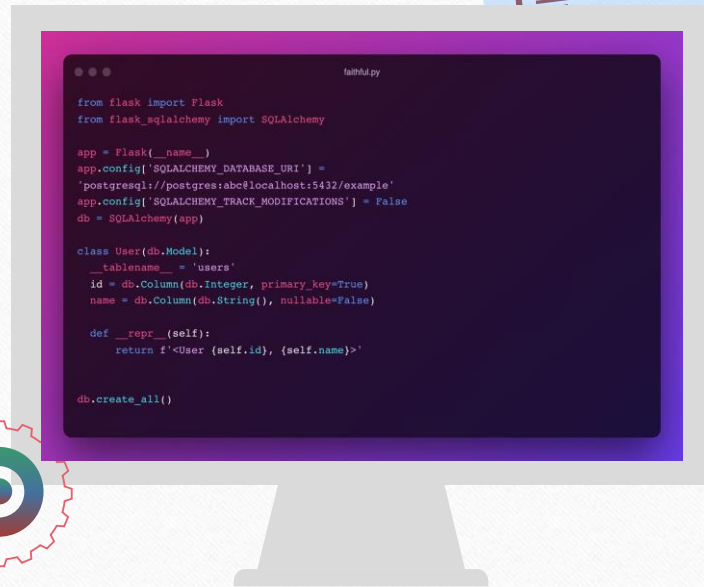

Command :(flask db upgrade) or :(flask db downgrade)

# Live Coding Session 3

We will be having our third live coding session for Migrations

# Migration Practice App

```
faithful_migration.py

from flask import Flask
from flask_sqlalchemy import SQLAlchemy
from flask_migrate import Migrate

app = Flask(__name__)
app.config['SQLALCHEMY_DATABASE_URI'] = 'sqlite:///'
app.config['SQLALCHEMY_TRACK_MODIFICATIONS'] = False
db = SQLAlchemy(app)

migrate = Migrate(app, db)

class Person(db.Model):
    __tablename__ = 'user'
    id = db.Column(db.Integer, primary_key=True)
    name = db.Column(db.String(), nullable=False)

    def __repr__(self):
        return f'<Person ID: {self.id}, name: {self.name}>'

@app.route('/')
def hello():
    person = Person.query.first()
    return f'Hello my name is {person.name}'
```

# WHAT ARE MIGRATIONS

Migrations refer to the management of incremental, reversible changes and version control to relational database schemas.

# WHY USE MIGRATIONS

- Migrations allow us to keep track of schema changes like how git tracks code changes
- We Can do a granular application of the schema change

03

# FLASK APP

Demo the usage of Flask-Migrate

# REQUIREMENTS

- Install flask-migrate
  - `pip install Flask-Migrate`
- Initialize flask-migrate
  - Using: `flask db init`
- Update our app to use Flask-Migrate
  - Import the migrate library and create a migrate instance

# REQUIREMENTS

- Sync your models  
Using: flask db migrate
- Upgrade  
Using: flask db upgrade
- Downgrades  
Using: flask db downgrade

04

What Next

# What Next

- Build a CRUD app with SQLAlchemy ORM - Part 1
- Build a CRUD app with SQLAlchemy ORM - Part 2
- Submit Project One: Fyyur

# Questions

Feedback

# Additional Resources

- [Flask Documentation](#)
- [Flask Migrate Documentation](#)
- [Flask SQLAlchemy Documentation](#)
- [A Premier on Database Relationships \(Understanding One-to-One, One-to-Many, and Many-to-Many\)](#)
- [Database Relationships](#)
- [SQLAlchemy Cheat Sheet](#)

# Additional Information

## Using Windows command prompt CMD

- Add PostgreSQL tools to Windows PATH

Add the PostgreSQL bin directory to the PATH variable

- create database called demo: create -U <super(dbuser)> <dbname>

*createdb -U postgres demo*

- Login into database called demo: psql -U <dbuser> -d <dbname>

*psql -U postgres -d demo*

# Additional Information

## Using A Virtual Environment

- Create a virtual environment

*python -m venv env*

- Activate a virtual Environment
  - For windows

*env\Scripts\activate*

- For linux and macOS:

*source env/bin/activate*

# Additional Information

To Run a Flask app in a file called hello.py

- Bash

```
export FLASK_APP=hello  
flask run
```

- PowerShell

```
$env:FLASK_APP = "hello"  
flask run
```

- CMD

```
set FLASK_APP=hello  
flask run
```

# Additional Information

**To Run interactive python terminal**

- Bash
  - > type python
  - > python -i
